CHAPTER 2 Protein Structure 29 As described in Chapter 1, the Watson-Crick Model helped to bridge a major gap between genetics and biochemistry, and in so doing helped to create the discipline of molecular biology.

SECTION Protein Structure and Function I

The cell (from Latin *cella*, meaning "small room") is the basic structural, functional, and biological unit of all known living organisms. A cell is the smallest unit of life. Cells are often called the "building blocks of life". The study of cells is called cell biology. Cells consist of cytoplasm enclosed within a membrane, which contains many biomolecules such as proteins and nucleic acids.

Unit cell. Crystal structure is described in terms of the geometry of arrangement of particles in the unit cell. The unit cell is defined as the smallest repeating unit having the full symmetry of the crystal structure. The geometry of the unit cell is defined as a parallelepiped, providing six lattice parameters taken as the lengths of the cell edges (a , b , c) and the angles between them (α , β , γ).

Four levels of structure determine the shape of proteins
aPrimary: the linear sequence of amino acids peptide bonds
aSecondary: the localized organization of parts of a polypeptide chain (e.g., the α -helix or β -sheet)

Lacing. Lacing is a mechanism to save space when storing data. It is typically used for small blocks of data (referred to as frames in matroska). There are 3 types of lacing : the Xiph one inspired by what is found in the Ogg container, the EBML one which is the same with sizes coded differently and the fixed-size one where the size is not coded.
